1 Details of the Analyses

This document was generated by R Markdown on 2021-12-10 using R version 4.0.5 (2021-03-31). The document provides the step-by-step analytical methods used in the manuscript by Anastasia Bernat (AVB) and Meredith Cenzer (MLC). Multiple draft scripts were written by AVB and MLC between 2020-03-01 and 2021-07-26 until being distilled and complied by AVB and code reviewed by MLC at the University of Chicago into this comprehensive script. All draft scripts can be viewed in the GitHub repository, SBB-dispersal (https://github.com/mlcenzer/SBB-dispersal), within the directory avbernat > Dispersal > Winter_2020 > stats .

All code and output from the statistical analyses are shown. Code for data cleaning and the generation of plots is not displayed, but can be viewed in the **appendix_B-flight_summary.Rmd** file and its accompanying sourced scripts. To repeat analyses and the generation of plots, all data files and sourced scripts should follow the directory structure presented in the SBB-dispersal repository.

1.1 Description of the Data

Soapberry bugs, Jadera haematoloma, were flight tested in the Fall 2019 (2019-10-15 to 2019-11-08) and Winter 2020 (2020-02-17 to 2020-03-10) seasons using a flight mill machine. Soapberry bugs were flight tested twice for either set time increments or multiple hours in the flight mill and observed from 8 AM to (5-8 PM) each day. For each trial, the mass, flight response, egg-laying response, distance, duration, average speed, and max speed of each soapberry bug was recorded and then processed.

All Python scripts used to process the flight records are located in the GitHub repository within the directory avbernat > Dispersal > Winter_2020 > windaq_processing . After trials, morphology measurements were taken for each bug. There are four morphology measurements: beak length, thorax width, wing length, and body length. The sex, wing morph (long-winged, shot-winged, or ambiguously-winged), host plant, and population of each bug were also recorded.

As a result of the experimental design, this document analyzes two main types of datasets: a full dataset and a unique dataset. A **full dataset** is a dataset where each row has a unique ID and trial type combination. A **unique dataset** is a dataset where each row has a unique ID because each trial has been grouped by ID. Examples are provided below. The advantage of generating a unique dataset is that changes between trials can be observed and analyzed.

1.2 Abbreviations Used in the Data and Code

- SBB soapberry bug, Jadera haematoloma
- S short-winged morph
- L long-winged morph
- LS or SL ambiguous wing morph
- T1 trial 1 of flight testing
- **T2** trial 2 of flight testing
- EWM eggs when massed, binary response (yes or no)
- host__ the host plant soapberry bugs were collected from, which was either *Koelreuteria elegans* or *Cardiospermum corindum*, occasionally called (and abbreviated) as goldenrain tree (GRT) or balloon vine (BV), respectively
- sym_dist distance from the local sympatric zone, which is demarked as Homestead

- wing2body a computed and unitless column that calculates the wing length divided by the body length of a soapberry bug
- sd standard deviation
- se standard error
- \mathbf{w}_{-} a column name that starts with \mathbf{w}_{-} is abbreviated from "wing". Example column: \mathbf{w}_{-} morph is "wing morph"

1.3 Data Transformations

- _b a column name that ends in _b is a column that has been recodified into binary data (0's and 1's). Example columns: flew_b, eggs_b
- _c a column name that ends in _c is a column that has been centered. Example columns: sex_c, host_c, avg_days_c
- _s a column name that ends in _s is a column that has been standardized. Example columns: wing2body_s, sym_dist_s, thorax_s
- avg_ a column name that starts in avg_ is a column that has been averaged across trial 1 (T1) and trial 2 (T2). Example columns: avg_mass, avg_days, avg_time_start, avg_rec_dur (exception: average_speed)
- _diff a column name that ends in _diff is a column that is the difference between T1 and T2 data values. Formula: data values
- _per a column name that ends in _per is a column that is the percent change between T1 and T2 (T2-T1) data values. Formula: (T2-T1)/T1 * 100.
- _logsqrt a column name that ends in _logsqrt is a column that has been normalized using a log-square-root transformation. Formula: log(sqrt(<data_column>))-mean(log(sqrt(<data_column>)). Example columns: avg_mass_logsqrt
- _logsqrt_i a column name that ends in _logsqrt_i is a column that has been normalized using a log-square-root transformation but its sign is the inverse of the column. Formula: log(sqrt(0.85-column))-mean(log(sqrt(0.85-column)). Example columns: wing2body_logsqrt_i

2 Winter 2020 Data Cleaning

2.1 Read Libraries

The flight response of *J. haematoloma* was analyzed using multivariate, generalized linear modeling (GLM) as implemented in the R packages lme4 and binom. All plots were generated using base R and supplemented with the popbio package to display logistic regressions and the rethinking package to display 95% confidence intervals of linear regressions. Additional R packages not show below but embedded in the sourced scripts are lubridate, chron, and dplyr. lubridate and chron both aid in datetime manipulation while dplry pipelines data grouping processes.

```
library(lme4) # fit regressions
library(rethinking) # Bayesian data analysis and plotting
library(popbio) # logistic regression plotting
library(binom) # binomial confidence intervals
```

2.2 Read Source Files

Each sourced script below aides in either data cleaning (read_flight_data(), center_data()) or multivariate GLM (model_comparisonsAIC(), get_model_probs(), catch_warnings()). Additionally, the function model_comparisonsAIC() takes in the path of a generic multi-factor script specific to

the GLM family and link function needed to build the predictive models. All aforementioned, sourced scripts are located in the **Rscr** folder.

2.3 Read the Data

The flight performance data read directly below are only from Winter 2020 flight trials. The read_flight_data() function standardizes data types and names of the ID, trial type, host plant, flight response, egg-laying response, sex, population, and wing morph inputs. The date, start time, and end time of trails are also converted into datetimes. Variables of interest like wing-to-body ratio are also calculated and centered. Using the clean_flight_data() function, all morphology, mass, and flight performance measurements are centered and/or standardized within the read_flight_data() function. Then, what is returned is a full dataset (n=758) that includes all bugs collected during Winter 2020 and a subset of the full dataset (n=614) that includes only bugs tested from the Winter 2020 collection.

The create_delta_data() function generates the unique dataset by grouping by ID. The function also computes trial differences, percent differences, and averages for variables of interest such as mass, flight response, egg-laying response, distance, and speed. Then, the unique data variables are centered and/or standardized.

```
data_path = paste0(dir,"/Dispersal/Winter_2020/stats/data/all_flight_data-Winter2020.csv")

data = read_flight_data(data_path) # centers each subset of data
data_all = data[[1]] # full dataset
data_tested = data[[2]] # subset of data_all, contains only bugs flight tested

# create the unique dataset
d <- create_delta_data(data_tested, remove_bugs_tested_once = FALSE)

# keep all bugs (even bugs only tested once), then re-center
dc <- center_data(d, is_not_unique_data = FALSE)</pre>
```

Example of a **full dataset** (each row has unique ID and trial type):

```
data_tested[c(1:2,400:401), c("ID", "trial_type")]
```

```
## ID trial_type
## 1 114 T1
## 2 318 T1
## 400 316 T2
## 401 416 T2
```

Example of a **unique dataset** (each row has unique ID):

```
dc[c(1:2,295:296), c("ID", "trial_type")]
```

```
## # A tibble: 4 x 2
   # Groups:
                ID [4]
##
     ID
            trial_type
##
     <fct> <list>
## 1 1
            <fct [2]>
            <fct [2]>
## 2 2
## 3 400
            <fct [2]>
## 4 401
            <fct [2]>
```

The datatype of the trial_type column is a list because when expanded out, it would show list(T1, T2).

3 Across-Trial Flight Response (T1 & T2)

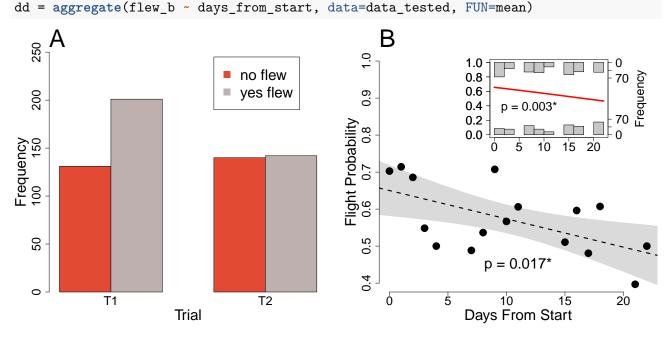

Flight response (yes flew or did not fly) was recorded and modeled. Multivariate, GLM was performed using the glm() function in the lme4 package. Models were compared using Akaike Information Criterion (AIC) and model selection was determined using Akaike weights. Model fit was further evaluated between two models using the anova() function.

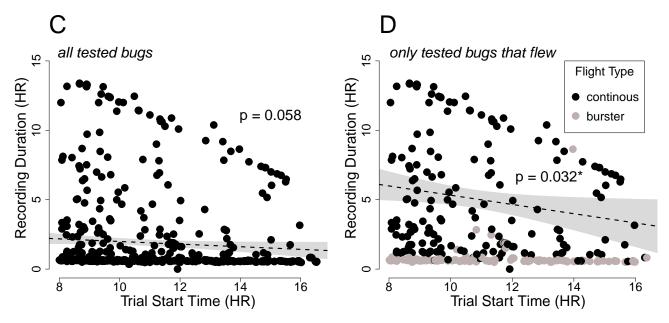

3.1 Experimental Effects

To determine how the design of the experiment affected flight response and/or performance, three design factors were modeled: trial type (T1 vs. T2), days from start, and trial start time.

3.1.1 Trial Type, Days from Start & Trial Start Time

```
# compute how many times flew yes or no per trial
binary_counts = table(data_tested$flew_b, data_tested$trial_type)[,2:3]
# aggregate by days since the trials began and flight response to determine flight prob
```

A & **B**. There was a negative effect of day a bug was tested (since the start of trials) on flight probability, but there was a significant effect only when the full dataset is considered. It is not significant for the unique dataset because days from start had to be averaged between trials. This is explored in the next section of the report. **C** & **D**. There was a negative effect of the trial start time on flight duration but only after removing bugs that did not fly (p = 0.031). Continuous flyers are driving this significant relationship (**D**).

3.2 Binomial Modeling

To understand SBB flight response, flight response across trials was modeled against sex, host plant, distance from the sympatric zone, wing-to-body ratio, and mass. This was done using the unique dataset.

Because the unique dataset was used, there exist multiple recorded counts of the number of times a SBB flew and did not fly between trials, T1 and T2. For that reason, we used cbind(num_flew, num_notflew) when modeling in order to account for all flight successes and failures for each individual.

Finally, we tested whether the data was over-dispersed, which could be resolved using a Quasibinomial:

```
# calculate the confidence interval for the mean of the data (Binomial vs. Quasibinomial)
fit <- glm(cbind(num_flew, num_notflew) ~ 1, family = binomial, data = dc)
plogis(confint(fit))

## 2.5 % 97.5 %
## 0.5191729 0.5976031

fit_q <- glm(cbind(num_flew, num_notflew) ~ 1, family = quasibinomial, data = dc)
plogis(confint(fit_q))

## 2.5 % 97.5 %
## 0.5108508 0.6056992

# estimate the dispersion parameter
summary(fit_q)$dispersion</pre>
```

[1] 1.464596

If the dispersion parameter is close to 1, the data is not over-dispersed, so there is not much of a necessity to apply a Quasibinomial model. Therefore, we selected the family as "binomial".

3.2.1 Average Days Since Start

For the unique dataset, average days since start (log-square-root transformed) was computed in order to determine how an experimental factor affected flight response. It proved to not be significant:

```
avg_days_model<-glm(cbind(num_flew,num_notflew)~avg_days_c, data=dc, family=binomial)
summary(avg_days_model)</pre>
```

```
##
## Call:
   glm(formula = cbind(num_flew, num_notflew) ~ avg_days_c, family = binomial,
       data = dc)
##

Average Days Since Start

10

15

5

0

Average days since start accounts for bugs who died before they could be tested twice, which would most likely lead to an early average day value. The rest of the bugs that were tested twice would most likely have a later average day value. This testing regime shapes the bimodal distribution seen in the histogram. Additionally, the advantage of this computed variable is that it controls for the fact that some bugs were tested once late, and some had been tested twice early. In turn, because we randomized test day, when repeated measures for each individual are combined across days, they

20

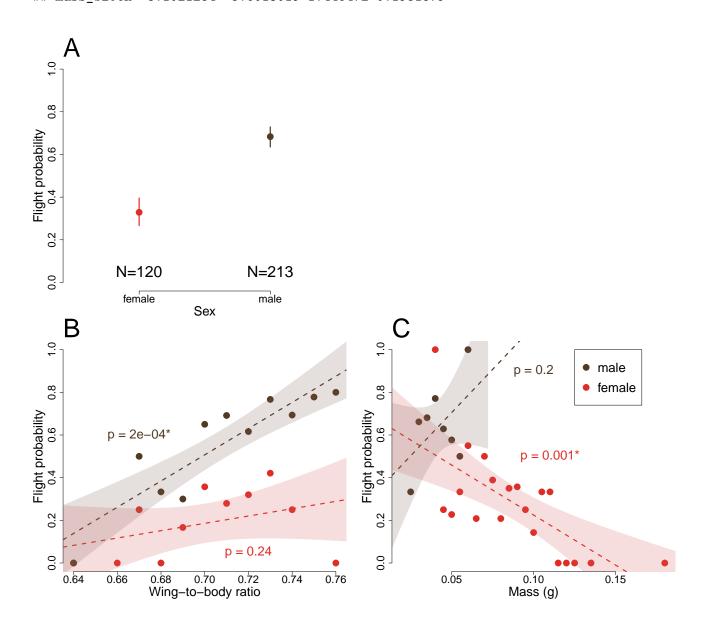

balance each other out. Thus, average days since start allows the multi-variate models, which control for repeated tests per ID number, to converge, and we can be confident that non-random mortality is not impacting flight response.

3.2.2 Single-Variate Effects sex, mass, wing2body

We used aggregated datasets for single-variate modeling and plotted significant effects below.

```
# tailoring variables for plotting
d$mass block=round(d$avg mass/0.005)*0.005
                                                # 0.005 q blocks
d$wing2body_block=round(d$wing2body, digits=2)
                                                # 0.01 blocks
d$days_block=round(d$avg_days, digits=0)
                                                # integer blocks
# aggregate data for plotting
dt=aggregate(flew_prob~sex, data=d, FUN=mean)
dt$trials=c(sum(d$num flew[d$sex=="F"]+d$num notflew[d$sex=="F"]),
            sum(d$num_flew[d$sex=="M"]+d$num_notflew[d$sex=="M"]))

4 Between-Trial Flight Response (T1 vs. T2)

4.1 Read Libraries

```
library(dplyr) # data manipulation
library(zoo) # data manipulation
library(nnet) # multinomial modeling
library(kableExtra) # table formatting
library(plot.matrix) # enables matrix/heatmap plotting
```

4.2 Read Source Files

4.3 Read the Data

```
# only keep bugs tested twice
d = create_delta_data(data_tested, remove_bugs_tested_once=TRUE)
```

4.4 Encodings & Signs

We aimed to model the probability of different delta flight response cases with sex, host plant, percent changes in mass, and percent changes in egg-laying response as predictors. Since the outcomes (or response variables) were no longer binomial, we used multi-categorical logit models. Below are the categorical encodings and/or signs used. See the Appendix for additional explanations and examples of computing multi-categorical logit models.

Delta Flight Response Key			
Event	Encoding		
flew in both trials	2		
flew in T2 only	1		
flew in neither trials	0		
flew in T1 only	-1		

Delta Percent Mass Key (%)		
Event	Sign	
gained % mass from T1 to T2	+	
no % mass change between trails	0	
lost % mass from T1 to T2	-	

Host Plant Key		
Host	Encoding	
Golden Rain Tree (GRT)	1	
Balloon Vine (BV)	-1	

Sex Key			
Sex	Encoding		
Female	1		
Male	-1		

4.5 Multinomial Modeling

4.5.1 Baseline

```
# remove any missing values for flight case or mass percent change between trials
df = d[with(d,!is.na(flight_case) & !is.na(mass_per)),]

# order the dataset by ascending mass percent change values
df = df[with(df, order(mass_per)),]

# relevel the flight case factors so as to set 0 as the first level.
df$flight_case = relevel(as.factor(df$flight_case), ref = "0")
```

4.5.2 Null Model

```
null = multinom(flight_case ~ 1, data = df)
## # weights: 8 (3 variable)
## initial value 385.389832
## iter 10 value 319.269929
